Working with multidimensional datasets in xarray

ALEX RAZOUMOV alex.razoumov@westgrid.ca

WestGrid webinar - Slides at http://bit.ly/389acaU

1/32

Zoom controls

- Please mute your microphone and camera unless you have a question
- To ask questions at any time, type in Chat, or Unmute to ask via audio
- Raise your hand in Participants

- This talk is being recorded
 - your name might appear in the recording (if you want, you can change it)
 - video will be posted at https://westgrid.github.io/trainingMaterials under one of the topics
- Email training@westgrid.ca

I assume basic familiarity with numpy arrays

As a quick recap (next few slides), numpy:

- provides a mechanism for uniform collections (aka arrays) of fixed-size, fixed-type items with contiguous allocation in memory
 - ⇒ large performance benefits (no reading of extra bits, no type checking, all compiled code)

I assume basic familiarity with numpy arrays

As a quick recap (next few slides), numpy:

- provides a mechanism for uniform collections (aka arrays) of fixed-size, fixed-type items with contiguous allocation in memory
 - ⇒ large performance benefits (no reading of extra bits, no type checking, all compiled code)
- arrays behave very differently from Python lists
- implements universal (vectorized) functions on a large number of elements
 - an operation on the array is applied to each element
 - statically typed, compiled routine
 - ⇒ almost always much faster than native Python code, especially for large and/or multidimensional arrays

WestGrid webinar - Slides at http://bit.ly/389acaU

⇒ use these whenever possible to replace native for loops

I assume basic familiarity with numpy arrays

As a quick recap (next few slides), numpy:

- provides a mechanism for uniform collections (aka arrays) of fixed-size, fixed-type items with contiguous allocation in memory
 - ⇒ large performance benefits (no reading of extra bits, no type checking, all compiled code)
- arrays behave very differently from Python lists
- implements universal (vectorized) functions on a large number of elements
 - an operation on the array is applied to each element
 - statically typed, compiled routine
 - ⇒ almost always much faster than native Python code, especially for large and/or multidimensional arrays
 - \Rightarrow use these whenever possible to replace native for loops
- provides the ability to operate between arrays of different sizes and shapes ("broadcasting")

I assume basic familiarity with numpy arrays

As a quick recap (next few slides), numpy:

- provides a mechanism for uniform collections (aka arrays) of fixed-size, fixed-type items with contiguous allocation in memory
 - ⇒ large performance benefits (no reading of extra bits, no type checking, all compiled code)
- arrays behave very differently from Python lists
- implements universal (vectorized) functions on a large number of elements
 - an operation on the array is applied to each element
 - statically typed, compiled routine
 - ⇒ almost always much faster than native Python code, especially for large and/or multidimensional arrays
 - ⇒ use these whenever possible to replace native for loops
- provides the ability to operate between arrays of different sizes and shapes ("broadcasting")
- provides linear algebra operations on mathematical arrays including linear solve and various decompositions

```
>>> import numpy as np
>>> a = np.arange(10)
>>> a
array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])
>>> a**2  # each element is a square of the corresponding element of a
array([0, 1, 4, 9, 16, 25, 36, 49, 64, 81])
>>> np.log10(a+1)
>>> np.log10(a+1)
```

```
>>> import numpy as np
>>> a
>>> a**2
                  # each element is a square of the corresponding element of a
>>> np.log10(a+1)
array([0., 0.30103, 0.47712125, 0.60205999, 0.69897, 0.77815125, 0.84509804, 0.90308999, 0.95424251, 1.])
>>> (a**2+a)/(a+1) # the result should effectively be a floating-version copy of a
>>> np.arange(10) / np.arange(1,11) # this is np.array([ 0/1, 1/2, 2/3, 3/4, ..., 9/10 ])
array([0., 0.5, 0.66666667, 0.75, 0.8, 0.83333333, 0.85714286, 0.875, 0.88888889, 0.9])
```

Let's check this summation

$$\sum_{k=1}^{\infty} \frac{k^2}{2^k} =$$

Let's check this summation

$$\sum_{k=1}^{\infty} \frac{k^2}{2^k} = 1$$

```
>>> k = np.arange(1,11)  # let's try the first 10 terms 
>>> sum(k**2/2**k) 5.857421875
```

let's try the first 10 terms

Let's check this summation

$$\sum_{k=1}^{\infty} \frac{k^2}{2^k} = \epsilon$$

```
>>> sum(k**2/2**k)
5.857421875
>>> k = np.arange(1,51)  # the first 50 terms
>>> sum(k**2/2**k)
5.99999999997597
```

Let's check this summation

$$\sum_{k=1}^{\infty} \frac{k^2}{2^k} = \epsilon$$

- 1. The shape of an array with fewer dimensions is padded with 1's on the left
- 2. Any array with shape equal to 1 in that dimension is stretched to match the other array's shape
- 3. If in any dimension the sizes disagree and neither is equal to 1, an error is raised

- 1. The shape of an array with fewer dimensions is padded with 1's on the left
- 2. Any array with shape equal to 1 in that dimension is stretched to match the other array's shape
- 3. If in any dimension the sizes disagree and neither is equal to 1, an error is raised

Example 1:
a:
$$(3,) \rightarrow (1,3) \rightarrow (3,3)$$

b: $(3,1) \rightarrow (3,1) \rightarrow (3,3)$
a+b: $\rightarrow (3,3)$

- 1. The shape of an array with fewer dimensions is padded with 1's on the left
- 2. Any array with shape equal to 1 in that dimension is stretched to match the other array's shape
- 3. If in any dimension the sizes disagree and neither is equal to 1, an error is raised

Example 1:		Example 2:	
a: $(3,) \rightarrow (1,3) \rightarrow (3,3)$	3,3)	$\overline{a:(3,)} \rightarrow (1,3) \rightarrow$	(3,3)
b: $(3,1) \to (3,1) \to (3,1)$	3,3)	b: $(3,2) \to (3,2) \to$	(3,2)
a+b:	\rightarrow (3,3)	a+b:	\rightarrow error

- 1. The shape of an array with fewer dimensions is padded with 1's on the left
- 2. Any array with shape equal to 1 in that dimension is stretched to match the other array's shape

      b: (3,1) \rightarrow (3,1) \rightarrow (3,3)
      b: (3,2) \rightarrow (3,2) \rightarrow (3,2)

      a+b:
      \rightarrow error
```

```
import numpy as np
import matplotlib.pyplot as plt
plt.figure(figsize=(12,12))
x = np.linspace(0, 5, 50)
y = np.linspace(0, 5, 50).reshape(50,1)
z = np.sin(x)*** + np.cos(5+x*y)*np.cos(x)  # broadcast!
plt.imshow(z)
plt.colorbar(shrink=0.8)
```

Many other Python packages were built on top of numpy

- scikit-image is a collection of algorithms for image processing
 - ightharpoonup each image is stored as width imes height imes 4 (R,G,B,lpha channels) numpy array
- pandas for (2D) tabular data manipulation
- vt for volumetric multi-resolution data
 - multiple subgrids at different resolution levels
 - any 3D field on each subgrid is stored as a 3D numpy array
 - any 3D field across all subgrids can be accessed as a flattened array
 - dozens of convenient functions to manipulate and visualize yt datasets
 - ► can import multi-resolution data from 20+ different file formats
 - ► fairly easy to convert generic array data into yt format
 - covered in our two earlier webinars:
 - "Using YT for analysis and visualization of volumetric data" (November 2018)
 - "Working with data objects in YT" (January 2019)
 - recordings at https://bit.ly/vispages

Xarray library

- Built on top of numpy and pandas
- Brings the power of pandas (easy data manipulation, I/O, plotting) to multidimensional arrays
- Does not support multi-resolution data out-of-the-box
 - i.e. you cannot define a single 3D field that spans multiple grids
 - b however, you can define multiple arrays on top of multiple grids inside the same dataset
- \checkmark Not limited to 3D \Rightarrow data of any dimensionality

- Two main data structures in xarray:
 - xarray.DataArray is a fancy, labelled version of numpy.ndarray
 - ► xarray.Dataset is a collection of multiple xarray.DataArray's that (usually) share dimensions

DataArray

DataArray

```
import xarray as xr
import numpy as np
data = xr.DataArrav(
    np.random.random(size=(4,3)),
    dims=("y", "x"), # we want 'y' to represent rows and 'x' columns
    coords={"x": [10,11,12],
            "v": [10,20,30,40]} # coordinate labels/values
print (data)
                 <xarray.DataArray (y: 4, x: 3)>
                 arrav([[0.8468579 , 0.79008336, 0.67300866],
                       [0.61169687, 0.82379812, 0.05382901],
                       [0.70889338, 0.01498123, 0.50806224],
                        [0.3437665 , 0.84299556, 0.89612048]])
                   * x (x) int64 10 11 12
                   * v (v) int64 10 20 30 40
```

access specific coordinate:

```
>>> data.size, data.dtype
(12, dtype('float64'))
             (x) int64 10 11 12
             (v) int64 10 20 30 40
```

access specific coordinate:

```
>>> data.coords['x']
             (x) int64 10 11 12
>>> data.coords['x'][1]
             int64 11
```

access specific coordinate:

             (x) int64 10 11 12
```

Subsetting arrays

Using the usual Python square brackets

- DataArray.isel() selects by coordinate index (single index, list, range)
- DataArray.sel() selects by coordinate value (single value, list, range)
- DataArray.interp() interpolates by coordinate value

- data.isel() is the same as data (no selection)
- Can refine selection by passing any number of arguments

- data.isel() is the same as data (no selection)
- Can refine selection by passing any number of arguments

- data.isel() is the same as data (no selection)
- Can refine selection by passing any number of arguments

- data.isel() is the same as data (no selection)
- Can refine selection by passing any number of arguments

```
>>> data.isel(y=1) # second row
                                                    >>> data.isel(y=0, x=[-2,-1])
                                                               # first row, last two columns
                                                    <xarray.DataArray (x: 2)>
            (x) int64 10 11 12
            int64 20
                                                                (x) int64 11 12
                                                      * X
                                                                int64 10
             q/cm^3
<class 'xarray.core.dataarray.DataArray'>
                                                    >>> data.isel(v=0, x=[-2,-1]).values
```

```
dtype('int64')
>>> data.x.values
array([10, 11, 12]
```

```
dtype('int64')
>>> data.x.values
>>> data.sel(x=10)
       0.506477, 0.730675681)
             int64 10
             (v) int64 10 20 30 40
              g/cm^3
```

```
dtype('int64')
>>> data.x.values
>>> data.sel(x=10)
<xarrav.DataArrav (v: 4)>
       0.506477, 0.730675681)
             int64 10
             (v) int64 10 20 30 40
              g/cm^3
```

```

array([10, 20, 30, 40])
             (y) int64 10 20 30 40
>>> data.sel(x=10, y=[30, 40]).values
```

```
>>> data.x.dtype
dtype('int64')
>>> data.x.values
>>> data.sel(x=10)
<xarrav.DataArrav (v: 4)>
       0.506477, 0.730675681)
             int64 10
             (y) int64 10 20 30 40
              g/cm^3
```

```
>>> data.v
array([10, 20, 30, 40])
              (y) int64 10 20 30 40
>>> data.sel(x=10, y=[30, 40]).values
>>> data.sel(v=slice(15,30))
                                   # only 15<=v<=30
       [0.506477 , 0.83279696, 0.1229428 ]])
              (x) int64 10 11 12
  * X
              (v) int64 20 30
               g/cm<sup>3</sup>
```

DataArray.interp() to interpolate by coordinate value

```
>>> data
<xarray.DataArray (y: 4, x: 3)>
             (x) int64 10 11 12
             (v) int64 10 20 30 40
              g/cm^3
                                # between 1st and 2nd rows, between 1st and 2nd columns
             float64 10.5
             int64 15
              q/cm^3
```

DataArray.interp() to interpolate by coordinate value

```
>>> data
<xarray.DataArray (y: 4, x: 3)>
             (x) int64 10 11 12
             (v) int64 10 20 30 40
             g/cm^3
                                # between 1st and 2nd rows, between 1st and 2nd columns
             float64 10.5
             int64 15
             q/cm^3
>>> data.interp(x=10.5, y=15, method="nearest").values
                                                         # closest neighbour
array(0.4515217)
```

DataArray.interp() to interpolate by coordinate value

```
>>> data
<xarray.DataArray (y: 4, x: 3)>
       [0.506477 , 0.83279696, 0.1229428 ], [0.73067568, 0.64027954, 0.999999 ]])
            (x) int64 10 11 12
            (v) int64 10 20 30 40
             g/cm^3
>>> data.interp(x=10.5, v=15)
                               # between 1st and 2nd rows, between 1st and 2nd columns
            float64 10.5
            int64 15
             q/cm^3
>>> data.interp(x=10.5, y=15, method="nearest").values
                                                       # closest neighbour
array(0.4515217)
>>> data.interp(y=15).values # between 1st and 2nd rows
```

Aggregate functions

array(0.61170573)

DataArray.groupby()

```
>>> columns
DataArrayGroupBy, grouped over 'x'
3 groups with labels 10, 11, 12.
```

>>> columns = data.groupby("x")

DataArray.groupby()

```
>>> columns = data.groupby("x")
DataArrayGroupBy, grouped over 'x'
3 groups with labels 10, 11, 12.
```

You can apply a function separately to each group:

```
>>> columns.map(lambda v: v.sum()/len(v))
                                              # could use v.mean() too with the same result
array([0.55905861, 0.60367705, 0.67238154])
                                              # same result as in the previous slide!
```

(x) int64 10 11 12

DataArray.groupby()

```
>>> columns = data.groupby("x")
>>> columns
DataArrayGroupBy, grouped over 'x'
3 groups with labels 10, 11, 12.
```

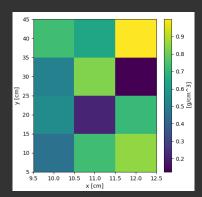

You can apply a function separately to each group:

(v) int64 10 20 30 40

Plotting

Matplotlib is integrated directly into xarray:

```
>>> data.plot(size=8)
<matplotlib.collections.QuadMesh object at 0x7fbf7a9c1a30>
>>> import matplotlib.pyplot as plt  # not needed inside Jupyter
>>> plt.show()  # not needed inside Jupyter
```

Plotting

0.85 0.80 0.75 0.70 0.65

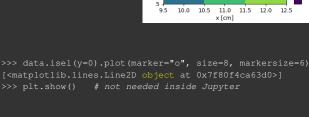

0.60 0.55 0.50

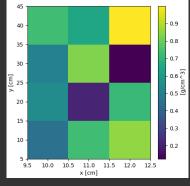

Matplotlib is integrated directly into xarray:

y = 10

10.00 10.25 10.50 10.75 11.00 11.25 11.50 11.75 12.00 x [cm]

```
>>> data.plot(size=8)
<matplotlib.collections.QuadMesh object at 0x7fbf7a9c1a30>
>>> import matplotlib.pyplot as plt  # not needed inside Jupyter
>>> plt.show()  # not needed inside Jupyter
```

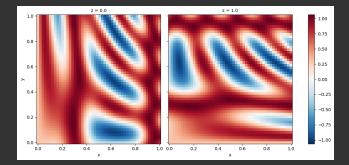

Create a 3D array

Let's create a function inside a unit cube $x, y, z \in [0, 1]$ on a 50³ grid:

```
import numpy as np
x = np.linspace(0, 1, n)
y = np.linspace(0, 1, n).reshape(n, 1)
z = np.linspace(0, 1, n).reshape(n, 1, 1)
f1 = np.sin(5*x)**8 + np.cos(5+25*x*y)*np.cos(5*x) # function at one side of the cube (z=0)
f2 = np.sin(5*y)**8 + np.cos(5+25*x*y)*np.cos(5*y) # rotated 90 degrees, other sise (z=1)
import xarray as xr
coords = {"z": z.flatten(), "y": y.flatten(), "x": x} # supply 1D array to all
rho = xr.DataArray(
    dims=("z", "v", "x"),
```

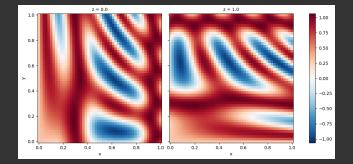

Plot this function

```
# rho.sel(z=[0,1]) is a 3D DataArray with two z values
# rho.sel(z=[0,1]).plot(size=8) will produce a histogram
rho.sel(z=[0,1]).plot(size=8, col="z")
import matplotlib.pyplot as plt  # not needed inside Jupyter
plt.show()  # not needed inside Jupyter
```

Plot this function

```
# rho.sel(z=[0,1]) is a 3D DataArray with two z values
# rho.sel(z=[0,1]).plot(size=8) will produce a histogram
rho.sel(z=[0,1]).plot(size=8, col="z")
import matplotlib.pyplot as plt # not needed inside Jupyter
                                  # not needed inside Jupyter
plt.show()
```

rho.to netcdf("rho.nc")

write to disk \Rightarrow let's view this function in ParaView!

Dataset

- xarray.Dataset is a collection of multiple DataArray's that (usually) share dimensions
- Create a dataset from scratch, starting from the existing code for rho DataArray:

```
import numpy as np
x = np.linspace(0, 1, n)
z = np.linspace(0, 1, n).reshape(n, 1, 1)
f1 = np.sin(5*x)**8 + np.cos(5+25*x*y)*np.cos(5*x) # function at one side of the cube (z=0)
f2 = np.sin(5*y)**8 + np.cos(5+25*x*y)*np.cos(5*y) # rotated 90 degrees, other sise (z=1)
import xarray as xr
coords = {"z": z.flatten(), "y": y,flatten(), "x": x} # supply 1D array to all
rho = xr.DataArray(f, dims=("z", "y", "x"), coords=coords)
temp = xr.DataArray(
                                             # standard normal distribution
     dims=("z", "v", "x"),
ds = xr.Dataset({"temperature": temp, "density": rho,
                     "bar": ("x", 200+np.arange(n)), "pi": np.pi})
```

Dataset (cont.)

Dataset (cont.)

```
<xarray.Dataset>
                 (z) float64 0.0 0.02041 0.04082 0.06122 ... 0.9592 0.9796 1.0
                  (y) float64 0.0 0.02041 0.04082 0.06122 ... 0.9592 0.9796 1.0
  * X
                  (x) float64 0.0 0.02041 0.04082 0.06122 ... 0.9592 0.9796 1.0
Data variables:

>>> ds.pi
array(3.14159265)
```

```
(x) float64 0.0 0.02041 0.04082 0.06122 ... 0.9592 0.9796 1.0
>>> ds.x[1].values
array(0.02040816)
                                  # this likely won't work!
>>> ds.density.sel(x=ds.x[1])
             (z) float64 0.0 0.02041 0.04082 0.06122 ... 0.9592 0.9796 1.0
             (y) float64 0.0 0.02041 0.04082 0.06122 ... 0.9592 0.9796 1.0
             float64 0.02041
```

2020-Sep-30

```
(x) float64 0.0 0.02041 0.04082 0.06122 ... 0.9592 0.9796 1.0
>>> ds.x[1].values
array(0.02040816)
                                  # this likely won't work!
>>> ds.density.sel(x=ds.x[1])
             (z) float64 0.0 0.02041 0.04082 0.06122 ... 0.9592 0.9796 1.0
             (y) float64 0.0 0.02041 0.04082 0.06122 ... 0.9592 0.9796 1.0
             float64 0.02041
```

Or you can use ds.density.isel(x=1)

or ds.density.sel(x=slice(0.01,0.03))

2020-Sep-30

Save the dataset to disk

ds.to_netcdf("cube.nc") ⇒ let's view this function in ParaView!

Before hitting apply, select Dimensions: (z,y,x)

Write to NetCDF in single precision (save disk space!)

Start with single-precision numpy arrays:

```
import numpy as np
import xarray as xr
n = 50
x = np.linspace(0, 1, n, dtype=np.float32)
v = np.linspace(0, 1, n, dtype=np.float32).reshape(n,1)
z = np.linspace(0, 1, n, dtype=np.float32).reshape(n,1,1)
f2 = np.sin(5*v)**8 + np.cos(5+25*x*v)*np.cos(5*v)
coords = {"z": z.flatten(), "v": v.flatten(), "x": x}
rho = xr.DataArray(f, dims=("z", "y", "x"), coords=coords)
temp = xr.DataArray(20 + 2*np.float32(np.random.randn(n,n,n)),
                    dims=("z", "v", "x"), coords=coords)
ds = xr.Dataset({"temperature": temp, "density": rho,
                 "bar": ("x", 200+np.arange(n,dtype=np.float32)), "pi": np.float32(np.pi)})
print(ds.density.dtype, ds.temperature.dtype, ds.bar.dtype, ds.pi.dtype)
          # float32 float32 float32 float32
ds.to netcdf("cubeSinglePrecision.nc")
```

Dataset in spherical geometry

```
To store the file in a NetCDF Climate and Forecast (CF) convention,
replace x, y, z with lat, lon, r (exact names not important)
and use ds.lat.attrs["units"] = "degrees_north"
and ds.lon.attrs["units"] = "degrees_east":
from numpy import linspace, sin, cos, float32, radians, random
import xarray as xr
nlat, nlon, nr = 181, 361, 30 # grid resolution
lat = linspace(-90, 90, nlat, dtype=float32)
lon = linspace(0, 360, nlon, dtype=float32).reshape(nlon,1)
r = linspace(0.9, 1, nr, dtype=float32).reshape(nr,1,1)
f = (1+0.8*cos(radians(lon))*cos(radians(lat))) * sin(radians(lat))**4 * r
coords = {"lat": lat, "lon": lon.flatten(), "r": r.flatten()}
rho = xr.DataArray(f, dims=("r", "lon", "lat"), coords=coords)
temp = xr.DataArray(20 + 2*float32(random.randn(nr,nlon,nlat)),
                   dims=("r", "lon", "lat"), coords=coords)
ds = xr.Dataset({"temperature": temp, "density": rho})
ds.lat.attrs["units"] = "degrees north" # important!
ds.lon.attrs["units"] = "degrees_east" # important!
ds.to_netcdf("spherical.nc")
```

⇒ let's load it into ParaView!

Time series data

Xarray relies on pandas functions for time-series functionality:

26 / 32

Time series data

Xarray relies on pandas functions for time-series functionality:

Time series data

Xarray relies on pandas functions for time-series functionality:

```
>>> import pandas as pd
>>> time = pd.date_range("2000-01-01", freq="D", periods=365*3+1) # 2000-Jan to 2002-Dec
DatetimeIndex(['2000-01-01', '2000-01-02', '2000-01-03', '2000-01-04',
               '2000-01-05', '2000-01-06', '2000-01-07', '2000-01-08',
               '2002-12-30', '2002-12-31'],
              dtvpe='datetime64[ns]', length=1096, freq='D')
>>> time.month
           dtype='int64', length=1096)
>>> time.dav
           dtype='int64', length=1096)
```

You can always type help (pd.date_range) or help(time)

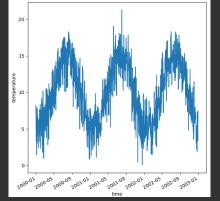

Time-dependent scalar dataset

```
import xarray as xr
import numpy as np
ntime = len(time)
temp = 10 + 5*np.sin((250+np.arange(ntime))/365.25*2*np.pi) + 2*np.random.randn(ntime)
ds = xr.Dataset({ "temperature": ("time", temp), "time": time })  # 1D function of time
ds.temperature.plot(size=5)
import matplotlib.pyplot as plt  # not needed inside Jupyter
plt.show()  # not needed inside Jupyter
```

Intro Xarray xarray.DataArray xarray.Dataset **Time** Geodata Summary ooooo o ooooooooo o**oooo** o o

Time-dependent scalar dataset

```
import xarray as xr
import numpy as np
ntime = len(time)
temp = 10 + 5*np.sin((250+np.arange(ntime))/365.25*2*np.pi) + 2*np.random.randn(ntime)
ds = xr.Dataset({ "temperature": ("time", temp), "time": time })  # 1D function of time
ds.temperature.plot(size=5)
import matplotlib.pyplot as plt  # not needed inside Jupyter
plt.show()  # not needed inside Jupyter
```

Time subsetting

last timestep

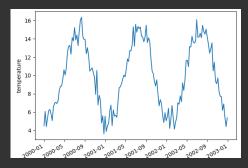

Time subsetting

```
>>> ds.isel(time=-1) # last timestep
                 datetime64[ns] 2002-12-31
Data variables:
>>> ds.sel(time="2002-12-22").temperature
array(5.24044602)
             datetime64[ns] 2002-12-22
```

Time subsetting

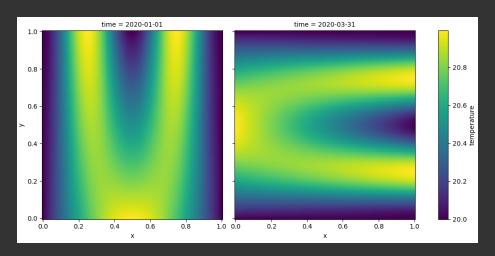

```
>>> ds.isel(time=-1)
                       # last timestep
                 datetime64[ns] 2002-12-31
Data variables:
                float64 6.399
>>> ds.sel(time="2002-12-22").temperature
array(5.24044602)
             datetime64[ns] 2002-12-22
```

```
>>> ds.resample(time='7D')
# from 1096 steps to 157 time groups
DatasetResample, grouped over '__resample_dim__'
157 groups with labels 2000-01-01, ..., 2002-12-28.
>>> weekly = ds.resample(time='7D').mean()
# compute mean for each group
>>> weekly.temperature.plot(size=8)
[<matplotlib.lines.Line2D object at 0x7fc8b8db3f70>]
>>> plt.show() # not needed inside Jupyter
```

Take our 3D dataset (recall cube.nc) and make it 2D+time:

```
import numpy as np
import pandas as pd
import xarray as xr
time = pd.date_range("2020-01-01", freq="D", periods=91) # January - March 2020
ntime = len(time)
             # spatial resolution in each dimension
X, Y = np.meshgrid(axis,axis) # 2D Cartesian meshes of x,y coordinates
   z = (t+0.5) / ntime # dimensionless time from 0 to 1
coords = {"time": time, "x": axis, "y": axis}
temp = xr.DataArray( # 2D array varying in time from initialState to finalState
    20 + f, dims=("time", "v", "x"), coords=coords
pres = xr.DataArray( # random 2D array
   100 + 10*np.random.randn(ntime,n,n), dims=("time","y","x"), coords=coords
ds = xr.Dataset({"temperature": temp, "pressure": pres})
ds.to_netcdf("evolution.nc")
```

⇒ let's play back evolution.nc in ParaView!

Earth's mantle convection

- Upcoming SciVis competition, will be announced towards the end of October
 - open to anyone (no research affiliation necessary)
 - ▶ please keep an eye on our emails and https://www.westgrid.ca
- Data courtesy of Hosein Shahnas and Russell Pysklywec at the UofToronto
 - simulation conducted using Compute Canada's Niagara cluster (SciNet)
 - each timestep saved as a separate multi-variable NetCDF file on a spherical grid
