#### Overlall themes

1/10

- Current maintenance
  - ► Cedar down for system software updates (today only)
  - /project expansion (/project unavailable March 1-4); you can still use /scratch for running jobs during this time
- Our explanations should not sound like excuses, and we do not want to project an idea that Cedar is unstable and users should avoid it
- Our goals are to:
  - provide as much uptime as possible
  - have all resources (CPUs, GPUs, memory, storage, bandwidth) to be utilized as much as possible
  - ► minimize gaps in scheduling between jobs
  - ► minimize turnaround for your jobs
  - provide all information in the system status (in case of downtime)
- When hardware/etc problems occur, we want you to know how you can work around them
- We want to show you how certain workflows can lead to system instabilities

## Major causes of system instability

- Node failures: a node needs rebooting
- File system problems: Lustre object storage servers can get overloaded with lots of small requests (more on this later); on Cedar we have
  - ► 4 object storage servers handling /home (slow) and /scratch (fast)
  - ► 10 object storage servers handling /project
  - ► these are paired into groups of two
    - $\circ$  one in a pair goes down  $\Rightarrow$  the other one will take over
    - $\circ$  both go down  $\Rightarrow$  the entire filesystem will hang
- Scheduler failures
  - ► Slurm can get overloaded with too many requests (more on this later)
- Oversubscription of nodes, GPUs
- No software stack synchronization between login and compute nodes
- Networking problems (within or outside our control)

#### What do you see?

- Sluggish jobs
- Jobs not starting / taking unusually long to start
  - also valid reasons why your job's starting time can be pushed into the future
- Slurm not responding, or producing unusual output
  - e.g. a job stuck in 'Prolog' R (running) state for a long time, not producing any output
- Shell not responding to simple commands or very slow
- Output files missing from your working directory
- Inside running jobs see "module not found"
  - typically requires manual intervention
- Cannot log in

# What can you do about these instabilities? **WEST**GRID

4/10

- Report problems to support@computecanada.ca with details:
  - system you are using
  - ► job IDs of affected jobs
  - detailed description of the problem
  - time/date it was first encountered
  - full path to one of the directories with the script and error files
    - o verify if you signed the consent that allow analysts to check your files (this will help resolve problems quickly instead of exchanging many emails)

#### Pay attention to login messages

- ► terminal output from anything in your ~/.bash\_profile or ~/.bashrc (e.g. when loading a module or activating a virtual environment) might force important system messages scroll past the top of the terminal
- ► these may contain both general system notices and /scratch purge notifications specifically for you
- Check http://status.computecanada.ca for updates and recent incidents

## What can you do? (cont.)

- Sometimes you could work around a temporary filesystem problem by submitting jobs from another filesystem
  - on Cedar /home,/scratch files are handled by different servers than /project (may not be always possible: performance)
- Do not delete and resubmit jobs that have been waiting in a queue for a long time until confirming with support@computecanada.ca
  - ► otherwise we can't analyze why a job is waiting, and priority may be lost
- Expect a backlog of jobs after a system problem
  - do not swamp the system with a bunch of new jobs be selective about what is most important to you
  - make sure that job parameters are chosen carefully to match the needs of particular jobs

#### These workflows will create problems

- Running anything CPU-intensive on the head node
- Submitting large number of jobs
- Issuing too many requests to the scheduler
  - ► classical example: running watch squeue ...
  - submitting thousands of jobs and then cancelling them
- Complex/unrealistic job dependencies can make Slurm unstable
- Not testing first on a small scale (and gradual scaling up)
  - ► large parallel jobs
  - many serial jobs and large job arrays
  - ► large computational problems in general
- Assuming perfect parallel scaling
  - ▶ your 64-core job may be slower than 32-core ...

#### Problematic workflows (cont.)

7/10

- Excessive and/or "bad" I/O, i.e. anything resulting in high load on Lustre object storage servers
  - avoid high IOps workflows: lots of small files, read/write in chunks smaller than 1MB, reading small blocks from large files
- Storing a large number of small files
  - ► organize your code's output
  - use tar or even better dar (http://dar.linux.free.fr, supports indexing, differential archives, encryption)
- Using nested parallelism in black-box pipelines
  - e.g. submitting serial jobs each of which launches multiple threads, sometimes asking for all cores on a node
  - ▶ your pipeline should be adapted to the cluster; if not sure, please talk to us
- Moving files from one filesystem to another (e.g. /home → /scratch) when close to quota can lead to data loss
  - ► use copy instead

#### Other best practices

- Checkpointing to be prepared for system failures
- Break your job into pieces (if possible)
- Only request resources (memory, running time) needed
  - ▶ with a bit of a cushion, maybe 115-120% of the measured values
  - ► use sacct or seff to estimate your completed code's memory usage
- Be aware that some filesystems are not backed up (e.g. /scratch), and some have a purge policy (/scratch)
   have a backup plan
- If a file's path changes, our backup system will interpret it as a new file
  unnecessary load on the filesystems
  - ▶ be careful with renaming large directories

#### Other best practices (cont.)

9 / 10

- If you still need to do lots of small I/O from inside your job:
  - use Slurm-generated directory \$SLURM\_TMPDIR (pointing to /localscratch/\${USER}.\${SLURM\_JOBID}.0 on a node's SSD) for both input and output
    - don't forget to move files out before your job terminates: everything in \$SLURM\_TMPDIR will be deleted
  - ► use \$TMPDIR RAM disk (pointing to /tmp)
    - o don't forget to allocate additional memory to your job
    - don't forget to move the results before your job terminates
- Port your workflow to another CC's general-purpose cluster, to run it there in case of failures
  - ► data management part may not be so easy, but Globus should help
  - also try to port your workflows (have accounts, appropriate input data, programs installed) to local clusters where available (Grex, Orcinus, Plato)
- If you received a /scratch purge warning, do *not* wait until the last minute to transfer data to local systems or other clusters
  - always pay attention to /scratch purge notices (email and system login message)

## Other best practices (cont.)

- Read the documentation about scheduling, running jobs, using modules, other topics
   https://docs.computecanada.ca
- Know as much as possible about your application, e.g. whether it is serial or parallel, and how it was parallelized (threaded vs. MPI)
